EdVyro Executive Analytics Capstone — Customer Churn Analysis
Use this as a simple speaking guide while recording your presentation. Read naturally; you do not need to memorize it.

Part 1 — Business Problem

Hello. This is my Executive Analytics Capstone on customer churn. The business question is: which customer groups should a subscription team contact first to reduce avoidable churn? My goal is to identify useful patterns in the supplied customer data and communicate them without overstating what the data can prove.

Part 2 — Data Analyzed

I analyzed the EdVyro customer churn sample. The dataset contains 15 customers and 11 fields, including customer characteristics, tenure, subscription type, charges, contract type, support tickets, payment method, and churn. In the supplied file, there are 7 customers marked as churned, giving an observed churn rate of 46.7 percent. I also checked the data quality: there are no missing cells and no duplicate rows in the supplied sample.

Part 3 — Five Important Insights

First, contract type shows different observed churn rates across groups. The observed results are: Month-to-Month: 7 customers, 100.0% churn; One Year: 4 customers, 0.0% churn; Two Year: 4 customers, 0.0% churn. Second, subscription type also shows differences in observed churn: Basic: 7 customers, 71.4% churn; Pro: 4 customers, 50.0% churn; Enterprise: 4 customers, 0.0% churn.

Third, tenure is useful for segmenting customers because the dataset contains customers with different lengths of tenure. These groups should be reviewed together with their observed churn rather than treated as proof that tenure causes churn. Fourth, support-ticket volume can be used as a retention-review signal. Customers with more support activity may deserve closer review, but this sample does not establish that support tickets cause churn. Fifth, monthly charges can help identify customer segments for further review. Charge level should be interpreted together with contract and subscription context rather than used alone to predict an individual customer's decision.

Part 4 — Recommended Actions

Based on these descriptive patterns, I would use the higher-observed-churn groups as a starting point for retention review. The practical next step is to validate these patterns on a larger customer population and then test targeted retention actions. The analysis should support human review, not automatically decide which customers must be contacted.

Part 5 — Expected Impact

I would not claim an exact number of customers saved from this sample. A future impact estimate should use explicit assumptions: the number of eligible customers, the baseline churn rate, the expected reduction in churn from an intervention, and the measurement period. Those assumptions can then be tested using a retention pilot or historical validation.

Part 6 — Limitations

There are important limitations. First, the sample contains only 15 customers, so small changes in the data can change group percentages substantially. Second, this is observational data, so differences between groups do not prove causation. Third, small subgroup counts are unstable and should not be generalized to the full customer population without further validation. Finally, factors not included in this dataset may also influence churn.

Closing

In summary, the analysis provides a small, descriptive view of customer churn patterns and identifies groups that can be prioritized for further retention review. The key message is to use the findings as a starting point for action and validation, rather than as proof of cause or a guaranteed forecast. Thank you.
